Tire Temperature Analysis. The Speed-Wiz Tire Temperature Analysis is a handy way to get a quick analysis of the tire temperatures measured from your vehicle. It's easy to make errors when you try to figure these out by hand. Speed-Wiz makes it foolproof. You get statistical analysis of the temperatures, plus chassis / setup recommendations to ...

Tire Temperature Analysis - Speed-Wiz

For determining the better performance of tire among air and nitrogen, the test was conducted by varying the inflation pressure, load and speed. The results of experimental analysis shows that the tire with nitrogen gas resulted in to lower rolling resistance and lower tire temperature as compared with air.

A coupled thermomechanical method is described where both the stiffness and the loss properties are updated as a function of strain, temperature, and frequency. Results for rolling resistance and steady state temperature distribution are compared with experiments for passenger and radial medium truck tires.

Finite Element Analysis of Mechanical and Temperature Field for a Rolling Tire Abstract: A numerical procedure has been applied to analyze the temperature distribution in a rolling tire. A 3D finite element model of a rolling tire is established to simulate the mechanical field under the certain inflation pressure, loading and velocity condition.

Average tire temperatures are found for each tire by adding the three temp readings together then dividing by three. In addition to the average temperature at each tire, you will want to know the average temperatures for the left side and right side, the front and the rear and the two diagonals.

2. Increase the air pressure in each tire during this phase of testing to provide less friction and more speed. Stop adding pressure when a tire shows a higher temp in the center of the tire 3. Using tire temps for assisting chassis setup, put at least 5-10 laps at full race speed on tires before taking any temperatures 4.

levels, the bias ply tires resulted in higher strains than the radial tires. This effect was probably due to temperature, 99 rather than tire type. The average pavement temperatures during the bias ply tests at these loads were from 6° to 10°F higher than those during the corresponding radial tire tests.

To dissipate heat racing tires are very thin. Thick tire rubber holds in heat and the potential for blistering increases. Tire engineers balance the rubber thickness with tire compounds to produce a package that considers car weight, corner speed, track abrasiveness, outside temperature, intended lap use and several other variables.
